This circular was prepared by G. L. Ross, Assistant Agronomist, J. F. Duncan, Assistant Agronomist, and D. W. Graffis, Professor of Forage Crops Extension. Data processing was done by the Statistical Laboratory of the Agronomy Department. S. G. Carmer, Professor of Biometry, supervised the analysis and preparation of the data.

Urbana, Illinois

December, 1973

Issued in furtherance of Cooperative Extension Work, Acts of May 8 and June 30, 1914, in cooperation with the U.S. Department of Agriculture. JOHN B. CLAAR, Director, Cooperative Extension Service, University of Illinois at Urbana-Champaign.

The Illinois Cooperative Extension Service provides equal opportunities in programs and employment.

PERFORMANCE OF COMMERCIAL CORN HYBRIDS IN ILLINOIS, 1973

(With 1971 and 1972 Listings)

CORN YIELDS IN ILLINOIS IN 1973 are estimated to average 105 bushels per acre. This is a decrease from the 1972 high of 110 bushels. Acreage planted increased to 9,580,000 acres. Thus the total production of corn in Illinois was 1.005 billion bushels, slightly more than in 1972 but below the 1971 production. Due to a wet fall in 1972, very little fall plowing and fertilizer spreading was completed during the winter. A wet March and April kept many farmers out of the fields until almost May. By the first week in May, only about 5 percent of the corn acreage had been planted. Frequent rains in May delayed planting of many acres until June and some of those that were planted in wet ground were slow in coming up and uneven in emergence.

Heavy localized rainfall in June resulted in flooding numerous areas, some more than once. But rainfall was adequate to provide a chance for a good corn crop. The temperature was high in June and July and the rainfall was erratic. August was moderate and rainfall was slight. It appeared that the crops were not hurt by drouth but still needed time for proper maturing. September was warm and the late-planted crops were helped by the absence of frost. October was dry and warm with only a few days with gusty winds. Stalk rot was not as noticeable as in 1972. There was little loss due to stalk rot because the dry harvest season allowed rapid, timely harvesting and no severe winds developed to lodge the infected corn. Harvest was virtually completed by November 15 throughout the state. There was an unusually large amount of fall plowing done throughout Illinois.

Plan of the Tests

Selection of entries. Each year all producers of hybrid seed corn in Illinois and surrounding states are invited to enter hybrids in the Illinois performance trials. This testing program is financed by a fee of 30 dollars for each hybrid at each location entered. Most of these hybrids are commercially available, although a few experimental hybrids are also entered. In 1973, a survey of popular hybrids was conducted among county extension advisers and the ten most popular hybrids at each location were added to the trials. These hybrids are marked by an asterisk (*) in the tables.

Number and location of tests. In 1973, 20 major tests were conducted at 11 locations in the state (see map on page 2). These sites represent major soil and climatic areas of the state.

Hybrids. Over 400 hybrids from 58 companies were tested in 1973. Seed for the trials was obtained by the University of Illinois staff from warehouse stocks whenever possible.

Field-plot design. Three or four replications of lattice design were used, thus assuring each entry an equal chance to show its merits.

Planting methods. All trials were planted by hand. All test fields except those at DeKalb, Carthage, Urbana, and Dixon Springs were part of larger corn-fields and thus were bordered by other corn. Each hybrid plot was overplanted 30 percent and later thinned to desired stands. Each plot was four rows wide and 28 feet long. The center two rows of each plot were harvested to determine yields.

Fertilization. All test fields were at a high level of fertility. Additional fertilizer was plowed down or side-dressed as needed to assure top yields.

Method of harvest. All plots were harvested with a self-propelled combine. Shelled corn from each plot was collected, weighed, and tested for moisture content. No allowance was made for corn that might have been lost in harvest.

Measuring Performance

Occasionally hybrids too late in maturity for a given area are entered in these tests. Such hybrids are often high in yield but their moisture content may make them poor choices for farm use unless proper drying or storage facilities are available.

Yield of grain. Shelled-corn weight and moisture percentage were measured for each plot of a hybrid and converted to bushels per acre of No. 2 shelled corn (15.5 percent moisture). An electronic moisture tester was used for all moisture readings.

Erect plants. The number of erect plants in each plot of a hybrid was counted at harvest time. Any plant leaning at an angle of more than 45 degrees or broken below the ear was considered lodged. Plants broken above the ear were considered erect.

Stand. In late June, plants in all plots on all fields were counted and the percent of stand was computed by comparing this number with the number of kernels planted. Plots with over 100-percent stand were thinned at this time. Stand differences may be caused by failure to germinate or by disease, insect injury, cultivation, or animal pest damage.

Plants per acre. Plants per acre were calculated

for each plot by using the percent stand obtained from plant counts. Differences in plants per acre and differences in percent stand are caused by the same factors.

Comparing hybrids. In any test of plant material, it is impossible to measure performance exactly. Samples may vary, soils may not be uniform, and many other conditions may produce variability. *Results of repeated tests, like those reported in this circular, are more reliable than those of a single year or a single strip test.* In general, a yield difference of a few bushels per acre is not significant in these tests. When one hybrid consistently outyields another at several test locations and over several years of testing, the chances are good that this difference is *real* and should be a consideration in choosing a hybrid. But yield alone is not enough. Consider also the grain moisture content, percentage of erect plants, percent stand, or plants per acre in comparing yields.

As an aid in comparing hybrids, certain statistical tests have been devised. D. B. Duncan¹ has outlined an approach to the problem of multiple comparisons when only two means are compared among a set of hybrid means. Certain factors not accounted for in previous tests of this type are included in Bayes L.S.D. This

¹ Duncan, D. B., "A Bayesian Approach to Multiple Comparisons," *Technometrics*, 7:171-222, 1965.

test is applied in the same manner as previous statistical tests used in these circulars. When two hybrids in a trial are compared, and the difference between them is greater than the tabulated L.S.D. value, then the hybrids are said to be "significantly different."

Growing Conditions at 1973 Test Fields

Extreme Northern Illinois: Woodstock. This test field represents the cool, humid area in northeastern Illinois. The test plot is on land operated by the Hughes Farms and Seed Company, Robert and Earl Hughes, Jr., cooperators. The soil is Proctor silt loam, a fertile, deep, well-drained, dark prairie soil. Very wet and cool weather in April and May slowed field work, and planting at this location was delayed until June. The shortened growing season resulted in smaller yields than expected.

Northern Illinois: DeKalb. This test is on the University of Illinois' Northern Illinois Research Center south of DeKalb. R. E. Bell is the field manager and D. L. Mulvaney is the area agronomist in charge of research at the Center. The soil is Flanagan silt loam, a dark-brown, adequately drained soil of high fertility. The growing season started off wet and cool but a few days without rain in May allowed many acres

Table 1. — General Information: Illinois Hybrid Corn Tests, 1973

of corn to be planted. Heavy rains in late May drowned out many low areas in the fields and they stayed wet until late June. June, July, and August had moderate rainfall and excellent growing conditions.

West North-Central Illinois: Galesburg. This test is located on the Hawkinson Farms, operated by Harold and Dave Hawkinson. The test field was a highly fertile, heavy-textured, Sable silty clay loam. Planting was timely as rainfall during May was below normal in the area. Growing conditions in June and July were ideal while August was low in rainfall and yields were less than anticipated. The corn matured earlier than usual and harvest was completed before lodging was severe.

East North-Central Illinois: Elwood. This test is on the Northeastern Illinois Agronomy Research Center in Will County. Dale Harshbarger is field manager and D. L. Mulvaney is in charge of research at the Center. The test is on an area of Drummer silty clay loam. Growing conditions started out excellent with timely planting and sufficient rainfall in May and June. However, the area received virtually no rain in July and August. Harvesting was started early because stalk rot and corn borer damage was causing noticeable stalk breakage and lodging.

West-Central Illinois: Carthage. This test is located on the Illinois Agronomy Research Center at Carthage in Hancock County. The soil is an Ipava silt loam. Planting was in late May due to wet soils in April and May. June rainfall was low and there was almost no rainfall in July. August rainfall was low and yields were about one-half of what was expected.

Central Illinois: Hartsburg. This test is located in Logan County on land adjoining the Hartsburg Agronomy Research field. The plot is on land operated by Lee Newby. The soil is Hartsburg silty loam. The field had almost ideal growing conditions until mid-August when a high wind caused severe lodging

throughout most of the area. Yields were very reflective of the severe lodging.

East-Central Illinois: Urbana. This test is located on the Agronomy South Farm of the University of Illinois at Urbana-Champaign in Champaign County. M. G. Oldham is the farm manager. Fields on which the test plots were grown are level, heavy-textured Drummer silty clay loam. Growing conditions at this location were ideal this year with over 8 inches of rain during August which boosted yields far above normal.

West South-Central Illinois: Greenfield. This test represents the moderately poorly drained soils of western south-central Illinois. The soil is Herrick silt loam. The plot is located between Palmyra and Greenfield in Macoupin County on a farm operated by C. H. Ross, Jr. The field was in an area that was very flat and poorly drained. Heavy rains in late May and early June stunted the corn and low rainfall in August prevented a normal yield.

Southern Illinois: Brownstown. This test is located at the University of Illinois' Brownstown Experimental Field in Fayette County. D. E. Millis is the area agronomist in charge of research at the field. The soil is Cisne silt loam, a poorly drained, gray prairie soil with a well-developed claypan. Growing conditions were excellent throughout the year and harvesting was completed before stalk breakage was severe.

Extreme Southern Illinois Bottomland: Dixon Springs. This test is located at the University's Dixon Springs Agricultural Center in Pope County with George McKibben cooperating. The test plot was located on Sharon silt loam, a light-colored, moderately well-drained, medium-textured bottomland soil. A planting was made on May 25. A few days later the plot was under 10 feet of water and it was not until June 26 that a successful planting was made. The growing season was short. A late harvest date allowed the corn to mature and dry adequately in the field. Lodging was severe on a number of varieties while not noticeable on others.

Extreme Southern Illinois Upland: Carbondale. The test at Carbondale represents the typical upland area in southern Illinois. The test is located on a field adjoining the Southern Illinois University Agronomy Research Center where Roy Browning and George Kapusta are cooperating agronomists. The soil type is Weir silt loam which is a shallow silty loam over claypan. Growing conditions were favorable up until mid-July. Then it was dry until late August resulting in very low yields of corn.
